RICHIE TRANSPORT SERVICES MANAGEMENT SYSTEM (RTS)

How your people will use Richie Transport Services

Who touches the system, what they do on it, and what the company gets out of it — a day-to-day guide for every role.

IN THIS DOCUMENT

- What the system does
- A day in the life of one shuttle run
- The controls that protect the company
- Questions the owner will ask
- The six roles and what each one owns
- What people actually do, and where
- What the company gets out of it
- How we start

PREPARED FOR

Prepared for the Managing Director

OCTOBER 2026

What the system does

Richie Transport Services runs the company shuttle service: one platform for planning routes, dispatching vehicles, carrying staff safely, and billing every client correctly. Two interfaces, one database, one set of rules.

Operations console

Where the service is run: the dispatch command centre, the trip board, the live map, the staff register, the vehicles, the money. Five of the six roles work here.

Driver app

What the driver uses in the vehicle: today's duty, the manifest, share position, board a passenger, report a problem. Built for a phone on a dashboard.

THE ONE RULE THAT EXPLAINS THE SYSTEM

You only see what your role allows, and each client's staff, trips and invoices stay under that client. Both are enforced by the server, not hidden in the menu — a role that cannot reach a screen is refused even if the address is typed by hand. The navigation is therefore a truthful picture of the job, not a smaller version of a bigger product.

Nothing in the service depends on a phone call or a spreadsheet. A request becomes a booking, a booking becomes a trip, a trip becomes a manifest, and a manifest becomes an invoice line. Every step is recorded, so the company can always answer who was carried, by which vehicle, under which agreement, and at what price.

WHAT THIS RELEASE COVERS

This release runs the service from one console and the driver app. The client-side logins — a client portal and a staff app — are switched off for now, and nothing was thrown away: the client companies, the branches, the staff register, the trips, the bookings and the invoices are all in the system already, and either role can be switched back on without rebuilding anything.

The six roles and what each one owns

The same code serves six roles. Each one opens the system on the screens that are actually their work — nothing more, nothing less.

ROLE	WHAT THEY ARE RESPONSIBLE FOR	THE SCREENS THEY GET
Super Administrator (20 screens)	The platform itself: who can use it, what the service agreements say, and the evidence of who did what.	Everything, including the audit trail, the user register, currencies and scheduled jobs.
Operations Manager (17)	The service: corridors, client contracts, the staff register, the plan, and the scheduled work that keeps it running.	Routes and stops, route optimisation, employees, corporate clients, fleet, drivers, compliance, operations.
Dispatcher (10)	The day: approving ride requests, assigning a driver and a vehicle, and watching the live board.	Live dispatch, trips, bookings, schedule, routes, safety and incidents.
Fleet Manager (7)	The vehicles: roadworthiness, fuel, maintenance and the incidents that take a bus off the road.	Fleet, drivers, compliance, safety and incidents.
Finance Officer (7)	The money: invoices, payroll, exchange rates and the reports the company is measured on.	Billing and payroll, reports, currencies, drivers for the cost base.
Driver (2)	Today's duty: start the journey, share the position, board the passenger, close the trip.	The driver app, and the boarding list.

The screen counts are read out of the running application, not typed by hand: a check in the build fails if a role can reach a different number of screens than this document says.

> **FOR THE OWNER**
> You do not need to learn six systems. You need one screen for the morning — the dashboard — and one report at the end of the month. Everything else in between belongs to the operations team and runs without you.

A day in the life of one shuttle run

This is the whole service in one table. It is how the roles hand over to each other, and how a passenger's journey is actually produced.

WHEN	WHO	WHAT HAPPENS
Previous week	Operations Manager	Adds joiners to the staff register, sets their shifts and pick-up zones. Sends a list for bulk upload.
Previous week	Operations Manager	Plans the corridor, runs route optimisation to order the stops, and agrees the client's service agreement.
Evening before	Dispatcher	Approves the ride requests, moves waitlisted passengers onto trips, confirms a driver and a vehicle for every run.
05:00	Fleet Manager	Confirms the vehicles are compliant and records the fuel.
06:00	Driver	Starts the journey and shares the position on the way in.
06:15	Dispatcher	Watches the live board. One bus is behind — the trip is opened and reassigned.
06:20	Driver	At the first stop, takes the boarding code and marks the passenger aboard.
06:45	Dispatcher	The manifest, the seat count and the live position are on one screen — no phone call needed to know where the bus is.
09:00	Dispatcher	Closes the trip. Anything that went wrong is logged as a safety incident.
Month end	Finance Officer	The invoice is raised automatically on the billing day, reviewed, and the report is exported.
Any time	Super Administrator	The audit trail answers: who did that, and when.

WHY THIS MATTERS COMMERCIALLY

Every handover above leaves a record. If a passenger complains, if a vehicle breaks down, or if a client disputes an invoice, the answer is a timestamped trail rather than a memory.

What people actually do, and where

The tasks that come up every day, and the role that owns each one.

TO DO THIS	THE SCREEN	OWNED BY
See whether the morning run is on time	Live Dispatch	Dispatcher
Assign a driver and a vehicle to a trip	Live Dispatch ? the trip	Dispatcher
Approve a passenger's ride request	Bookings	Dispatcher
Add a new employee to a client	Employees	Operations, Admin
Set up a client and its contract	Corporate Clients	Operations, Admin
Plan the route for a corridor	Routes & Stops	Operations, Dispatcher
Choose the best order for the stops	Route Optimisation	Operations, Dispatcher
Check a vehicle is roadworthy, log fuel	Compliance	Fleet Manager
Record a breakdown or an accident	Safety & Incidents	Dispatcher, Fleet
Raise this month's invoice	Billing & Payroll	Finance Officer
Change an exchange rate	Currencies	Finance Officer
Produce a report or a PDF	Reports	Finance, Operations
See who changed what	Audit Trail	Super Administrator only
Add or suspend a user	Settings & Users	Admin, Operations
Start my journey, board a passenger	Driver App	Driver

Two shortcuts make it fast on day one. The command palette (Ctrl+K or ?K) searches every screen and the live data — trips, bookings, vehicles, drivers, employees — and only offers results the signed-in role is allowed to see. And the top bar carries the live trip ticker, the notifications and the theme switch, so the state of the service is always one glance away.

The controls that protect the company

A transport operation is a liability operation. These are the controls that come with the system rather than with extra work.

Clients are kept apart

Every query is scoped on the server. A client's staff, trips, bookings and invoices are held under that client, and no one reaches another company by any route.

Access is refused, not hidden

A role that cannot use a screen is turned away by the server even if the address is typed by hand. The menu is not a security control — the server is.

Every change is recorded

User accounts, contracts, rates, bookings, trips, incidents and invoices all leave an audit trail with the person, the time and the detail.

Boarding codes

A passenger shows a code that only that booking carries. It proves the right person boarded the right vehicle, and it settles the argument before it starts.

Live position and alerts

Vehicles report their position, trips are flagged delayed or broken down, and the dispatcher sees it on the board and on the map without a phone call.

Vehicle compliance and fuel

Roadworthiness, inspections, fuel and incidents are recorded against the vehicle, so the question "is this bus fit to carry our staff?" has an answer.

Billing that reconciles

Invoices are raised automatically on the agreed billing day from the trips actually run, with the service agreement applied and the currency handled.

Data that is looked after

Sessions, one-time codes and sign-in attempts are purged on a schedule, positions are aged out, and the database is backed up automatically and pruned.

SIGN-IN PROTECTION

Passwords are stored as scrypt hashes, sessions are held as tokens in an httpOnly cookie, five failed attempts lock an account for fifteen minutes, and privileged accounts need a second factor. The test sign-in route used by the automated checks is closed unless it is explicitly switched on.

What the company gets out of it

The reports are the point. These are the numbers the service can be run on and reported on — every one of them comes out of the system rather than out of a notebook.

THE MEASURE	THE QUESTION IT ANSWERS	WHERE IT COMES FROM
On-time arrivals	Are staff collected when they said they would be?	Scheduled against actual departure, per route
Average delay	How far behind is the service running?	Trip deviation and the incident log
Cost per passenger	Is the shuttle cheaper than the alternatives?	Invoices and payroll over passengers carried
Seat fill, by vehicle	Are the buses half empty?	Seats sold against capacity, per vehicle
Revenue per client	What does each contract cost, and what is still owed?	Invoiced, collected and outstanding, by client
Driver performance	Are the drivers good enough to keep?	Trips, on-time record, passengers carried and rating
Safety and maintenance	Any incidents, and what did the fleet cost?	Incident log with the action taken, and maintenance spend
Completed journeys	How many journeys did we actually make?	Completed trips and their manifests

The monthly pack for the owner is one page: what was carried, what it cost, how the buses performed, and anything that needs a decision. It is exported from Reports as a PDF or a spreadsheet, and it is produced from the same records the service ran on.

> **THE COMMERCIAL ARGUMENT**
> Consolidated staff transport is cheaper than a fuel allowance or a fleet of individual vehicles, and it is the only version of the service that can be measured. The system makes the saving visible instead of theoretical.

Questions the owner will ask

QUESTION	ANSWER
A driver calls in sick at 5 a.m. — what happens?	The dispatcher sees the unassigned trip on the board, assigns another driver and a vehicle, and the change is recorded on the trip.
A passenger is late for the bus.	The trip waits or departs per the corridor rule, and the manifest records who boarded. The boarding code is what settles it.
A new employee joins next Monday.	The operations team adds them once in the staff register and sets their shift and pick-up zone. They appear on the right runs automatically from then on.
A client disputes an invoice.	The invoice is raised from the trips that ran, under the agreed agreement. The bookings and the trip records show exactly what was carried.
Can one client's staff see another client's data?	No. The scope is enforced on every query on the server, not by hiding links, and each client's records are held under that client.
What happens if the internet drops in the vehicle?	The driver app queues the updates offline and replays them when the connection returns, without duplicating records.
Who can see the audit trail?	The Super Administrator alone. It records every change with the person and the time, and cannot be edited by the people it watches.
Is the data ours?	The client records belong to the client, are separated by tenant, and are exportable at any time.

How we start

Three stages. Each one ends with a number that proves the next stage is worth doing.

1. Stage one — pilot (four weeks). Two branches, the routes they already run, the current drivers. The company sees the daily board, the first invoices and the first month-end pack. Exit measure: every trip in the pilot captured in the system, and the invoice reconciled against the old process.
2. Stage two — rollout. Every branch and every shift on the system, the operations team adding staff through the register instead of a spreadsheet, finance paying from generated invoices. Exit measure: one invoice run, one report, no parallel spreadsheets.
3. Stage three — optimise. Route optimisation, seat-fill targets, vehicle utilisation, and a service-agreement review for each client. Exit measure: a cost per passenger that is measured, not estimated.

> **WHAT WE NEED FROM YOU**
> The staff register and the shifts for the first two branches, the current routes and their times, the vehicles and their drivers, and the client agreements with the billing basis. Everything else is already in the system.

The platform runs on one server with an embedded database — no database server to install, no cloud account to open. It is deployed as a container, it is backed up automatically, and it can be operated by a single administrator with a browser. The driver app installs on a phone and keeps working when the network drops.

Richie Transport Services Management System. Six roles, two interfaces, 42 database tables, live dispatch, automated billing and a full audit trail. This document describes how the system is used; the technical detail is in the project documentation.
